Outline

- **Introduction**
- **Motivation and Prior Work**
- **Definitions**
- **Wirelength Prediction**
- **Routing Demand Prediction**
- **Conclusion**

Introduction

- **Interconnect Prediction**
 - breaks repetitive design convergence loop
 - helps in performing early feasibility studies
- **A-Priori Prediction**
 - is done before placement stage
 - is used to provide congestion map, wirelength metrics
 - can be used for architecture evaluation

Scope of This Work

- A-Priori *wirelength* and *interconnect* prediction for island-style FPGAs
- Bounding box prediction for *all* wires
 - Identifying important circuit characteristics which constrain placement
 - Assumes that wirelength is minimized during placement
- Routing demand estimation
 - Channel Width calculation
- No prior characterization of placement/router

Prior Work

- Rent's Rule [TVLSI 2000, Bakoglu]
 - Interconnect prediction builds models for architecture, circuit and placement
 - Can calculate average/total wirelength, congestion etc.
- Sechen [ICCAD 87]
 - Average wirelength of optimized placements
 - For all possible bounding boxes, enumerate all possible positions for sources and sinks to calculate average wirelength of the whole netlist
- Hamada et al. [DAC 92]
 - Break down nets into cliques and perform neighborhood analysis on them
 - Placement is considered a stochastic process
 - Wirelength distribution is calculated
- Bodapati et al. [SLIP 00]
 - Bounding box estimates using structural analysis
 - Needs calibration of placement/router

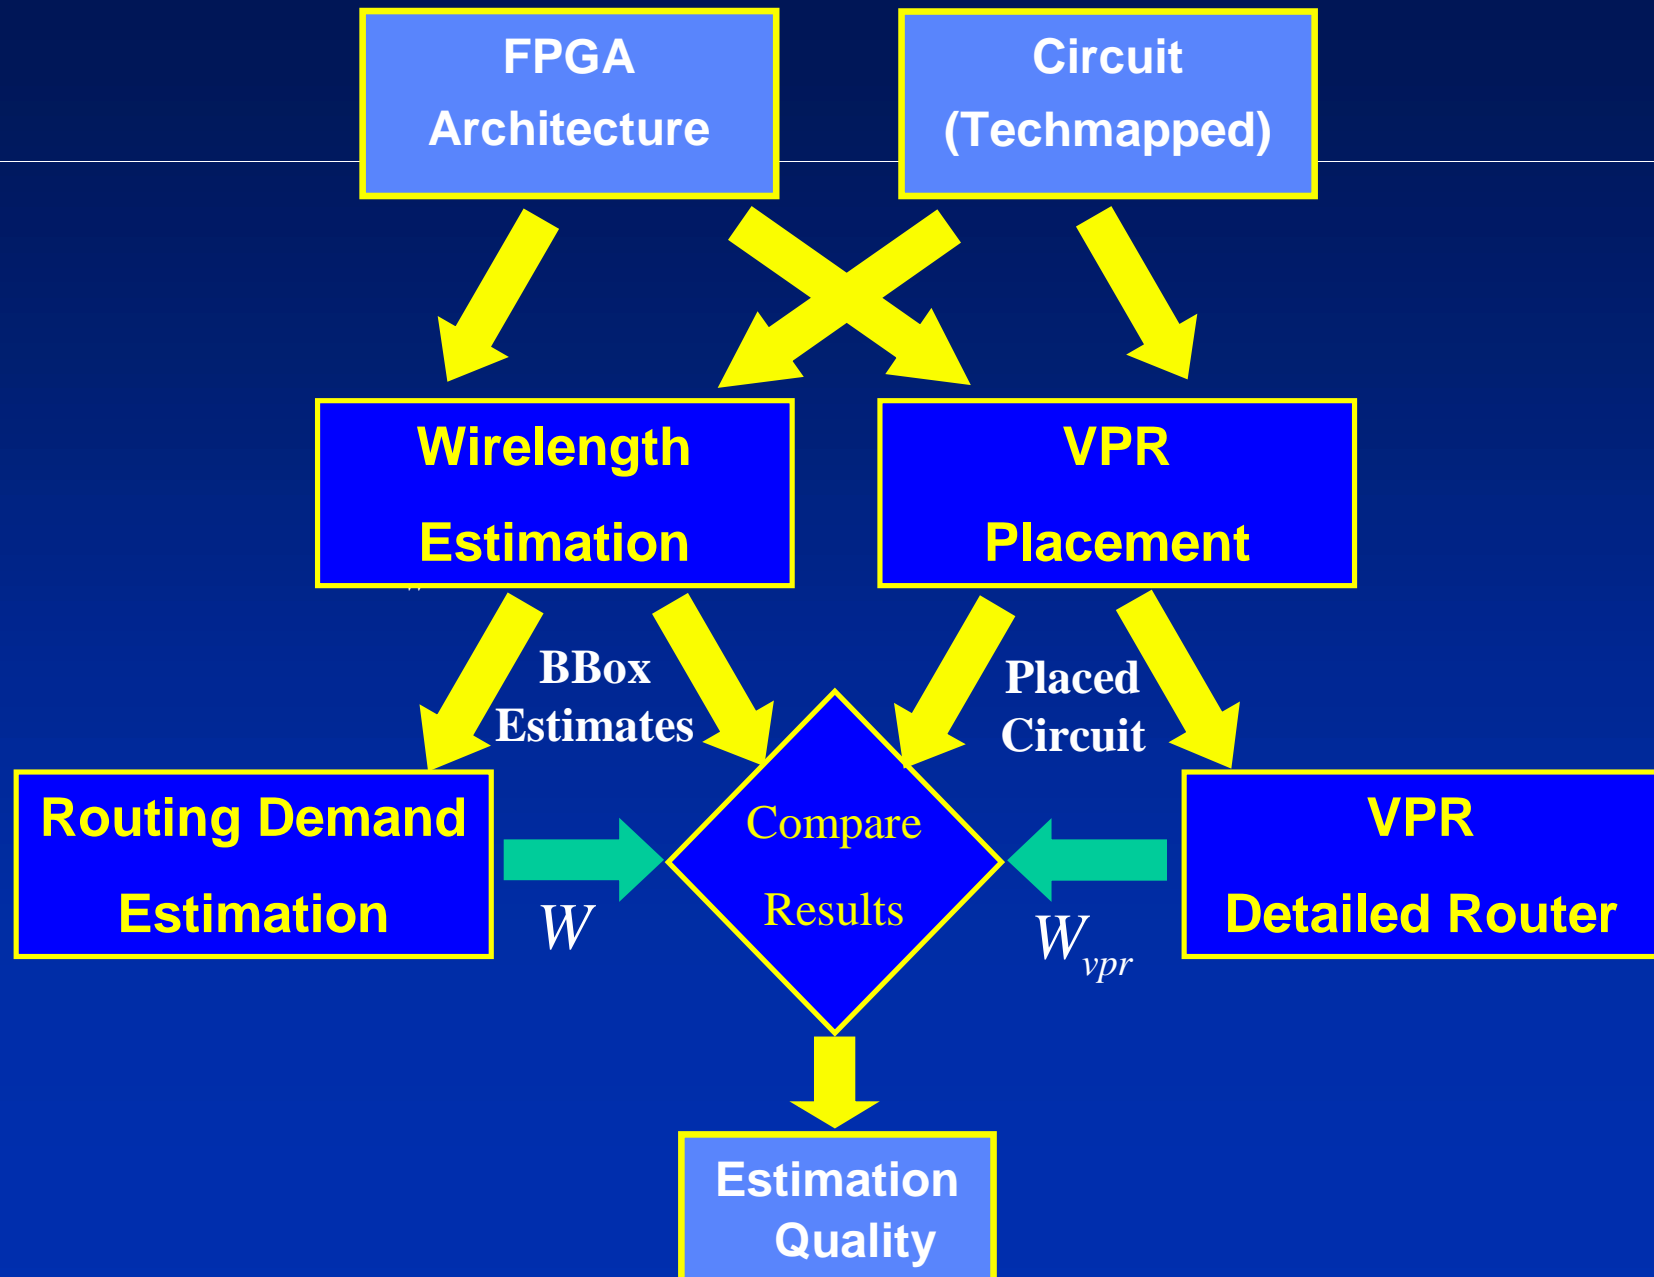

Motivation

- **Average wirelength is not sufficient**
 - Rent's rule, Sechen and Hamada et al. report only these figures
- **Individual wirelength is useful**
 - Logic synthesis, floorplanners
- **Congestion metrics should be quantifiable**
 - Very important for FPGAs
 - Channel Width requirements for routers
 - To avoid the chicken and egg problem

Island Style FPGA

Methodology

Definitions [CIRC - TCAD 98, TVLSI 02]

- Combinational level $c(x)$ of a node is :

$$c(x) = \max(c(x') \mid x' \in \text{fanin}(x)) + 1$$

- $cmax = \max(c(x))$

- Sequential level $s(x)$ of a node is :

$$s(x) = \begin{cases} 0 & ; x \text{ is a PI-node} \\ s(x') + 1; & x \text{ is a FF-node with input } x' \\ \min(s(x') \mid x' \in \text{fanin}(x)) & ; \text{ otherwise} \end{cases}$$

- $smax = \max(s(x))$;

- Shape : A vector

- $\text{Shape}[i] = c_0 \mathbf{L} c_{cmax}$; $c_i =$ number of nodes in level i
- For sequential circuits, the combinational shape vector in each level are concatenated back to back

Definitions(2)

- Reconvergence R_{xy}
 - Has multiple paths from x to y
 - x is the origin of reconvergence
 - y is the destination of reconvergence
 - Always contained within one sequential level

- Number of reconvergences

RN_{xy} = Number of paths from x to y

- Length of reconvergence

$$RO_{xy}(x) = RI_{xy}(y) = \frac{1}{RN_{xy}} \sum_{p \in P_{xy}} l(p)$$

P_{xy} is the path-set from x to y
 $l(p)$ is the length of path p

$$R_{BE} : RN = 2$$

$$l(p_1 = B \rightarrow C \rightarrow E) = 2$$

$$l(p_2 = B \rightarrow D \rightarrow E) = 2$$

$$RO_{BE}(B) = RI_{BE}(E) = 2$$

$$R_{AG} : RN = 2$$

$$l(p_1 = A \rightarrow (BE) \rightarrow G) = 3$$

$$l(p_2 = A \rightarrow F \rightarrow G) = 2$$

$$RO_{AG}(A) = RI_{AG}(G) = 2.5$$

Overview of Our Methodology

Reconvergence

```

Wirelength Estimation

- Wirelength of a circuit depends on
 - Structural properties of the circuit
 - Placement of the circuit
- Nets from **Input** pads usually feed more nodes than the other nodes
 - Hence, classify the nets as **logic nets** and **IO-nets** and treat them separately
- Wirelength of an individual net **N** will depend on
 - Number of terminals – t_N
 - Interaction with other nets

Phase 1 - Minimum Span for Logic Nets

- Assume a net N is tightly placed. Wirelength is optimal when
 - Source is placed in the center
 - All sinks are tightly packed around the source
- Minimum span L is entirely dependent only on t_N

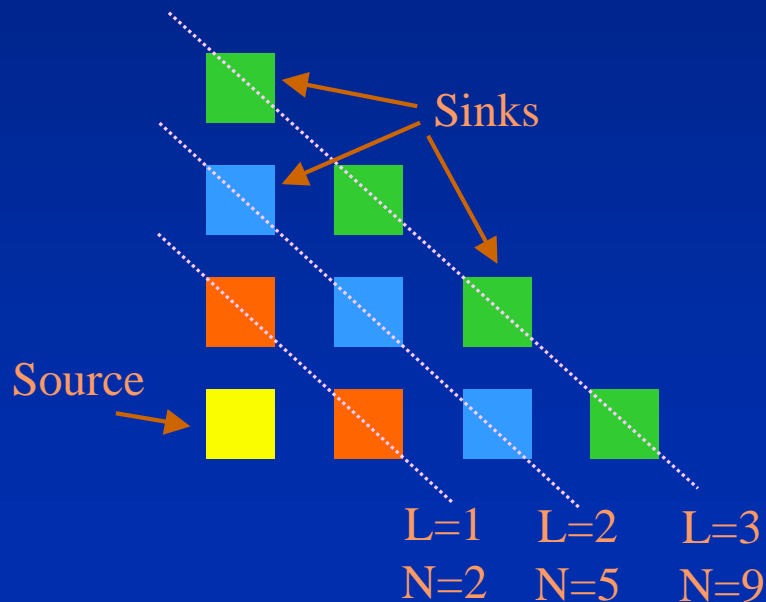

$$4 + 8 + 12 + L + 4 \cdot L \geq t_N$$

$$L = \frac{\sqrt{1 + 2 \cdot t_N + 1}}{2}$$

Phase 1 - Minimum Span for IO-Nets

- Input pads are placed along the periphery
- IO-Nets have many sinks usually, and the location of the Input pads cannot be guessed
- Assume the Input pad is in the corner of the FPGA
 - Worst-case calculation of wirelength
- Tight placement of sinks around the pad

$$2 + 3 + 4 + L + L \geq t_N$$

$$L = \sqrt{2 \cdot t_N + 9/4} - 1/2$$

Phase 2 – Dilation of Nets

- Tight placement is always **not** possible
 - **Push** and **Pull** from other nets are ignored
- Net N has no incident reconvergences \Rightarrow no dilation
- N has incident reconvergences \Rightarrow other nets pull the cells away \Rightarrow dilation
- Net dilation is based on reconvergences on its immediate neighborhood : source, sinks, fanin

- For any node that is an origin of any reconvergence R_{x^*} , let the **out-weight** be

$$RO(x) = \frac{\sum RO_{x^*}}{\sum RN_{x^*}}$$

the average length of all out-bound reconvergences

- For all node that is a destination of any reconvergence R_{*y} , let the **in-weight** be

$$RI(y) = \frac{\sum RI_{*y}}{\sum RN_{*y}}$$

the average length of all in-bound reconvergences

Dilation Factor

- Raw weight of a node x is $RW'(x) = RI(x) + RO(x)$
- Flip-Flops have many incident reconvergences, hence an adjustment w.r.to LUT-size k

$$RW(x) = \begin{cases} \log_k RW'(x); & \text{if } x \text{ is a FF-node} \\ RW'(x) & ; \text{otherwise} \end{cases}$$

- Dilation on a net N with v_N as its source is

$$R(N) = \left(\sum_{x \in \text{fanin}(v_N)} RW(x) + \sum_{y \in \text{fanout}(v_N)} RW(y) + RW(v_N) \right) / t_N$$

- Similar to flip-flops, IO-Nets have large weights, hence an empirical value for IO-Nets

$$R(N) = \begin{cases} 3/\sqrt{2} & ; \text{if } N \text{ is a IO-Net} \\ R'(N) & ; \text{otherwise} \end{cases}$$

Phase 3 – Uniform Distribution

- Let p be the position in which *Shape* vector has the maximum value
- The nodes in this level are so many in number that they are expected to be uniformly distributed in the layout
 - The nodes in this level are not connected to each other
 - They are however strongly connected to the other nodes
- If a node has more than one such cell, the net will dilate more

Spread Due To Uniform Distribution

- **SP** = Set of nodes in the peak level
- **N** = Minimum required FPGA size
- Construct a hypothetical grid which has only one cell from **SP**
- The hypothetical grid size is related to the FPGA dimension as
$$G = \frac{N}{\sqrt{|SP|}}$$
- If a net **N** has some nodes in **SP** then the span must respect the uniform distribution assumption
- The uniformity factor is calculated as

$$U = \sqrt{|SP \cap fanout(v_N)|} \cdot G$$

Bounding Box Span of a Net

- The bounding box span of the net N depends on

- L – the minimum span of the net
- $R(N)$ – the dilation of the net due to reconvergences
- U – the uniformity factor

- The horizontal span of the net N is

$$HSpan(N) = \begin{cases} \max(L, U) & ; \text{if } R(N) < 1 \\ \max(L \times R(N), U) & ; \text{if } R(N) > 1 \end{cases}$$

- The vertical span of the net is same as $HSpan$
- The total span of the net is

$$Span(N) = HSpan(N) + VSpan(N) = 2 \cdot HSpan(N)$$

Individual Wirelengths

Circuit : *misex3*

Error in Span Vs Number of Nets

Routing Demand Estimation

- We use RISA to calculate number of routing elements needed
 - An empirical technique based on wirelength of nets with various terminal sizes
 - The routing demand is based on two factors
 - q - an empirical factor dependent on t_N
 - Bounding Box Sizes
- The actual routing demand for a net N is calculated as

$$D_h^N = q \times \frac{1}{HSpan(N)}; D_v^N = q \times \frac{1}{VSpan(N)}$$

Definitions

- C = Number of Logic Blocks
- nIO = Number of I/O blocks
- If the circuit is placed in the smallest possible device, its width (also height) is given as

$$N = \max(nIO/4, \sqrt{C})$$

- TD = Total Number of Routing Elements Needed

$$TD = \sum_N D_h^N + D_v^N$$

Channel Width Estimation for Pad Unconstrained Circuits

■ Pad-Unconstrained Circuits

- $N = \sqrt{C}$
- TD routing elements are uniformly distributed across the device

- Channel width W is calculated as $W = \frac{TD}{C} = \frac{TD}{N \times N}$

Channel Width Estimation for Pad Constrained Circuits

■ Pad-Constrained Circuits

- $N = nIO/4$
- Assume that all the logic blocks are placed in the center – consistent with modern placers
- However, **TD** routing elements should be distributed across the whole device

- Channel width **W** is calculated as
$$W = \frac{TD}{C} \times \frac{\sqrt{C}}{N} = \frac{TD}{\sqrt{C} \times N}$$

Experimentation - Other Methods Compared

- RISA [ICCAD 94, DAC 2002]
 - Post-placement technique
 - Add up demands for different sites in the layout and find the maximum channel width
- Yang et al. [ISPD 2001]
 - Rentian Method
 - Extended for FPGAs in [8]
 - Recursive partitioning of circuit and layout
 - Worst-case congestion analysis on the boundaries

Summary

- Identified some important circuit characteristics which dictate placement
 - **Push** and **Pull** from reconvergences stretch wires
 - Reconvergences capture more than the local neighborhood of cells
 - 30% more accuracy with reconvergences factored in
- Bounding box prediction is accurate within 11.6% of post-placement lengths
- Channel widths are predicted within 6% of post-route results

Illustration of Bounding Box Calculation

Phase 3

Node D and Node C are in peak level and hence should spread out

Phase 1

Sinks are tightly placed around the source node

Phase 2

Node A has high reconvergence weight. Pulled away from the net

Overview of Our Methodology

Reconvergence Analysis

- Perform reconvergence analysis within different sequential levels
- Assign weights to nodes based on reconvergences

Bounding Box Estimation

- For every net
 - Calculate the minimum possible bounding box
 - Find dilation factor using reconvergence weights
 - Uniformly distribute *peak nodes*
 - Calculate the actual span using these 3 factors

Track Width Estimation

- Calculate the number of routing elements required using RISA for every net
- Calculate the total number of routing elements
- Distribute this routing demand evenly in the layout to obtain maximum channel width
